

Math 122 Wednesday, September 21

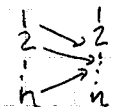

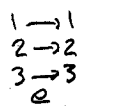

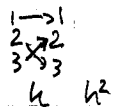

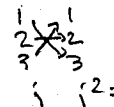

Recall a group  $G$  has a map  $g, h \mapsto g \cdot h \in G$  associative,  $e$  identity,  $g \mapsto g^{-1}$

ex:  $G = GL_n(\mathbb{R}) =$  invertible  $n \times n$  real matrices  
 ↪ "general linear" group

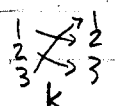

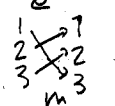

ex:  $T$  a set  $G = \text{Aut}(T) = \{ \text{bijections } g: T \rightarrow T \}$  multiplication = composition  
 $e =$  identity map inverse = inverse map

$T = \mathbb{R}^n = \{ (x_1, \dots, x_n) : x_i \in \mathbb{R} \}$   $GL_n(\mathbb{R}) \subset \text{Aut}(T)$  subset of linear bijections  $A \begin{pmatrix} x_1 \\ \vdots \\ x_n \end{pmatrix} = \begin{pmatrix} y_1 \\ \vdots \\ y_n \end{pmatrix}$

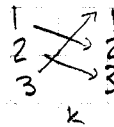

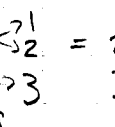

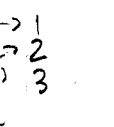

$T = \{ 1, 2, \dots, n \}$  finite set then  $\text{Aut}(T) = S_n$ , the symmetric group on  $n$  letters

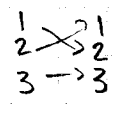

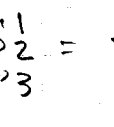

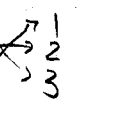

$g \in S_n$  works by  e.g. in  $S_3$    $g^2 = e$    $h^2 = e$    $j^2 = e$

recall  $\#S_n = n!$  so this is all of  $S_3$ .

  $k$    $m$   $m = k^2$   $km = k^3 = e$

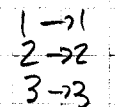

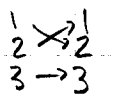

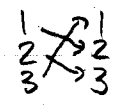

Claim  $S_3$  is a non-abelian group.

$g \cdot k = h$    $g$    $k$   $=$    $h$

but  $k \cdot g = j$    $k$    $g$   $=$    $j$

defn The number of elements of a finite group (written  $\#G$  or  $|G|$ ) is called the order of  $G$ .

Cycle notation for  $S_n$

eg.   $e = (1)(2)(3)$    $g = (12)(3)$    $k = (123)$

for shorthand can write  $(12)$  for  $(12)(3)$  etc  
 so  $S_3 = \{ e, (12), (23), (13), (123), (132) \}$

generally the cycle notation for  $g \in S_n$   $g = (1 \ g(1) \ g(g(1)) \ \dots)$  eg.   $(124)(35)$

defn Given  $g \in G$  the order of  $g$  is the smallest  $n \in \mathbb{N}$  such that  $g^n = e$ .

eg.  $(12)$  has order 2,  $(123)$  has order 3

Given an object (group, set, ring, vector space, ...) we are also interested in sub-object, quotient-object, map between objects = homomorphism

defn Subgroup  $H \subset G$  is

- 1) a subset
- 2) closed under multiplication
- 3) contains  $e$
- 4) contains  $h^{-1}$  for all  $h \in H$

ex: in  $S_3$ ,  $H = \{e, (12)\}$  is a subgroup

$H = \{e, (123)\}$  is not closed under multiplication or inverses but  $H' = \{e, (123), (132)\}$  is.

other subgroups:  $\{e, (13)\}$ ,  $\{e, (23)\}$ ,  $\{e\}$ ,  $G$

ex:  $GL_n(\mathbb{R}) \subset \text{Aut}(\mathbb{R}^n)$  is a subgroup because matrix multiplication is the same as composition of linear transformations.

Closed because composition of two linear maps is linear.

General theme: often subgroups arise by preserving something (eg. linearity)

also  $H = \{e, (12)\}$  is the subgroup of  $S_3$  that fixes "3".

$H = \{e, (123), (132)\}$  fixes something too but this is harder to see

Let  $H \subset S_n$  be all permutations that fix  $n$ , a subgroup of order  $(n-1)!$

[next time we'll say  $H$  is isomorphic to  $S_{n-1}$ ]

Consider the abelian group  $\mathbb{Z}$  under addition [note: here "multiplication" is written "+"]  
 $e = 0$   $(n)^{-1} = -n$

Goal: classify all  $H \subset \mathbb{Z}$  obvious subgroups:  $H = \mathbb{Z}$ ,  $H = \{0\}$

$H = \{\dots, -4, -2, 0, 2, 4, 6, \dots\}$  even numbers

note  $H = \{\text{odd numbers}\}$  not closed, doesn't contain 0.

more generally take  $H = n\mathbb{Z} = \{\text{numbers divisible by } n\} = \{nk \mid k \in \mathbb{Z}\}$

note:  $n\mathbb{Z} = (-n)\mathbb{Z}$  so assume  $n \geq 0$

Thm Any subgroup  $H \subset \mathbb{Z}$  has the form  $n\mathbb{Z}$  with  $n \geq 0$  uniquely determined by  $H$ .

Pf: Let  $H$  be a subgroup. If  $H = \{0\}$  take  $n=0$ . Otherwise  $H$  contains some positive integers. Let  $n$  be the smallest positive integer contained in  $H$ . Then claim:  $H = n\mathbb{Z}$ . Clearly  $H \supset n\mathbb{Z}$  by closure under addition and inverses. Take any  $h \geq 1$  in  $H$ , and write  $h = nk + r$  with  $0 \leq r < n$ . Claim  $r=0$ . Note  $h, nk \in H$  so  $h - nk \in H$  by closure under addition and inversion. So  $r \in H$ . If  $r \neq 0$  this contradicts minimality of  $n$ . So  $h = nk \Rightarrow h \in n\mathbb{Z}$ . For negative  $h$  consider the inverse so we're done.

More generally given  $g \in G$  there is a subgroup  $H$  generated by  $g$  which is the smallest subgroup which contains  $g$

$$\langle g \rangle = \{ e, g, g^{-1}, g^2, g^{-2}, g^3, \dots \} \quad g^0 = e, g^a \cdot g^b = g^{a+b}, (g^a)^{-1} = g^{-a}$$

in  $S_3$  every subgroup other than  $S_3$  is generated by one element

in  $\mathbb{Z}$  every subgroup  $n\mathbb{Z} = \langle n \rangle$  is generated by one element
