

# CALCULUS AND ECONOMICS

Oliver Knill

April 26, 2013

# TOTAL AND MARGINAL COST

$C(x)$  Total Cost

$C'(x)$  Marginal Cost

$x$  = quantity of goods sold

**Example:** Where is the total cost  $C(x)$  maximal, if

$$C(x) = x^3 - 4x$$

# THE STRAWBERRY THEOREM

see Heckner/Kretschmer:  
Don't worry about Micro

Marginal Cost  $f(x)$ :  
of one Strawberry

Total Cost  $F(x)$   
of  $x$  strawberries

Average Cost  $g(x) = F(x)/x$

Expected cost of one strawberry if  
 $x$  strawberries are present.

# SUMMARY SO FAR

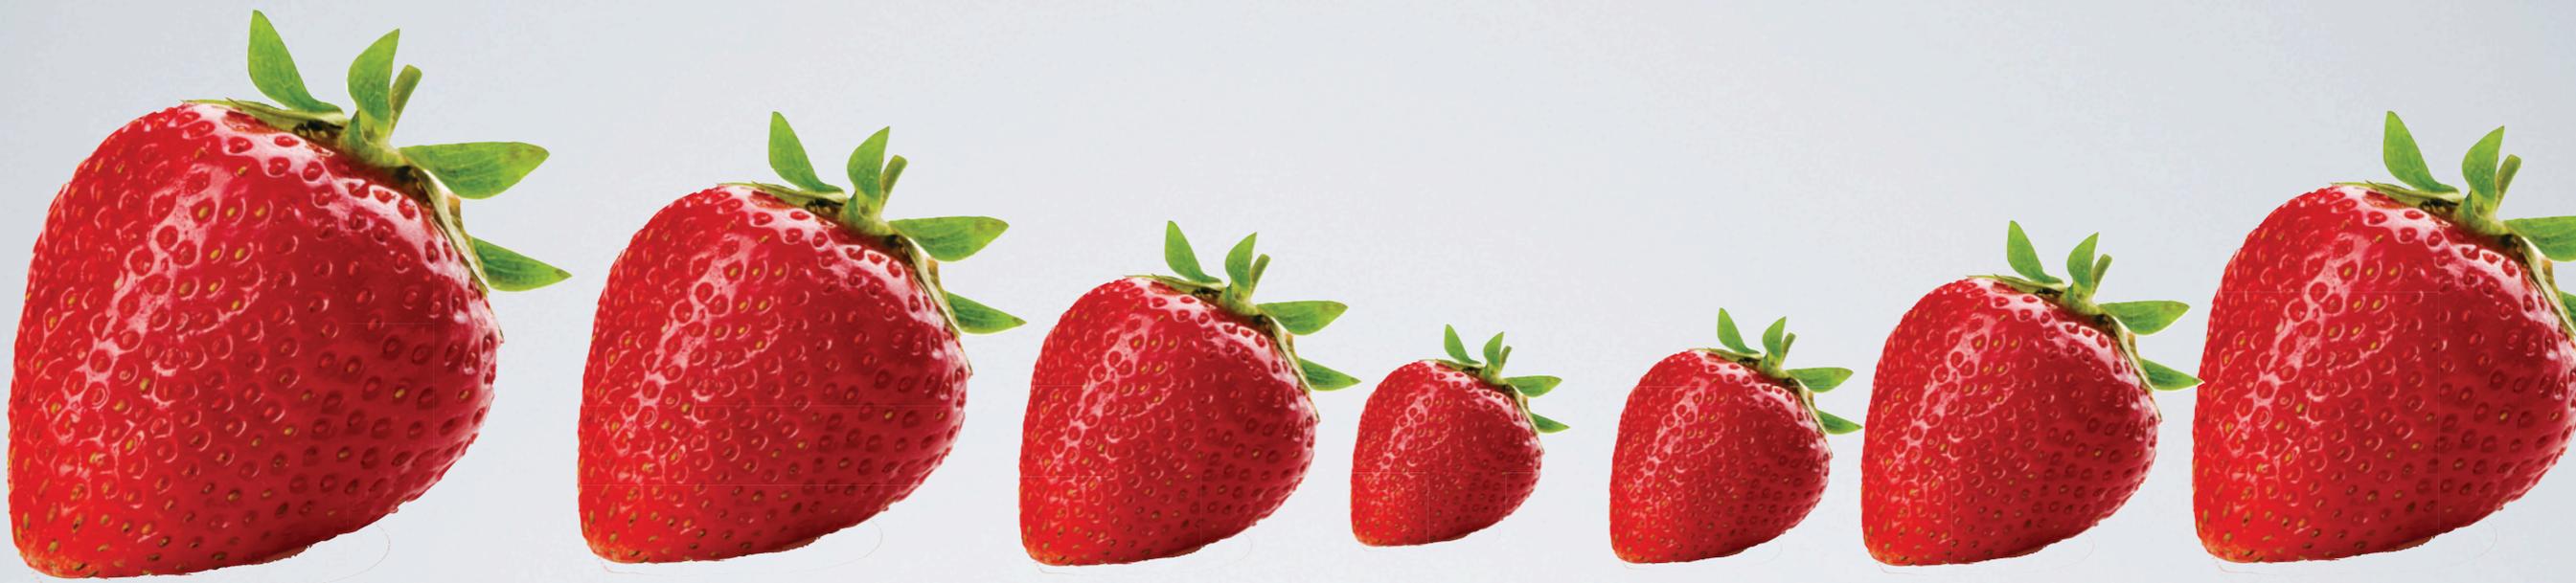

TOTAL COST:  $F(x)$

MARGINAL COST:  $f(x)$

AVERAGE COST:  $g(x) = F(x)/x$

Formulas to  
remember:

$$F'(x) = f(x)$$
$$F(x)/x = g(x)$$

$x=1$                        $x=2$                        $x=3$                        $x=4$                        $x=5$                        $x=6$                        $x$

total cost  $F(3)$   
cost of the strawberry 3

marginal cost  $f(3)$ :  
cost of the strawberry 3

# THE STRAWBERRY THEOREM

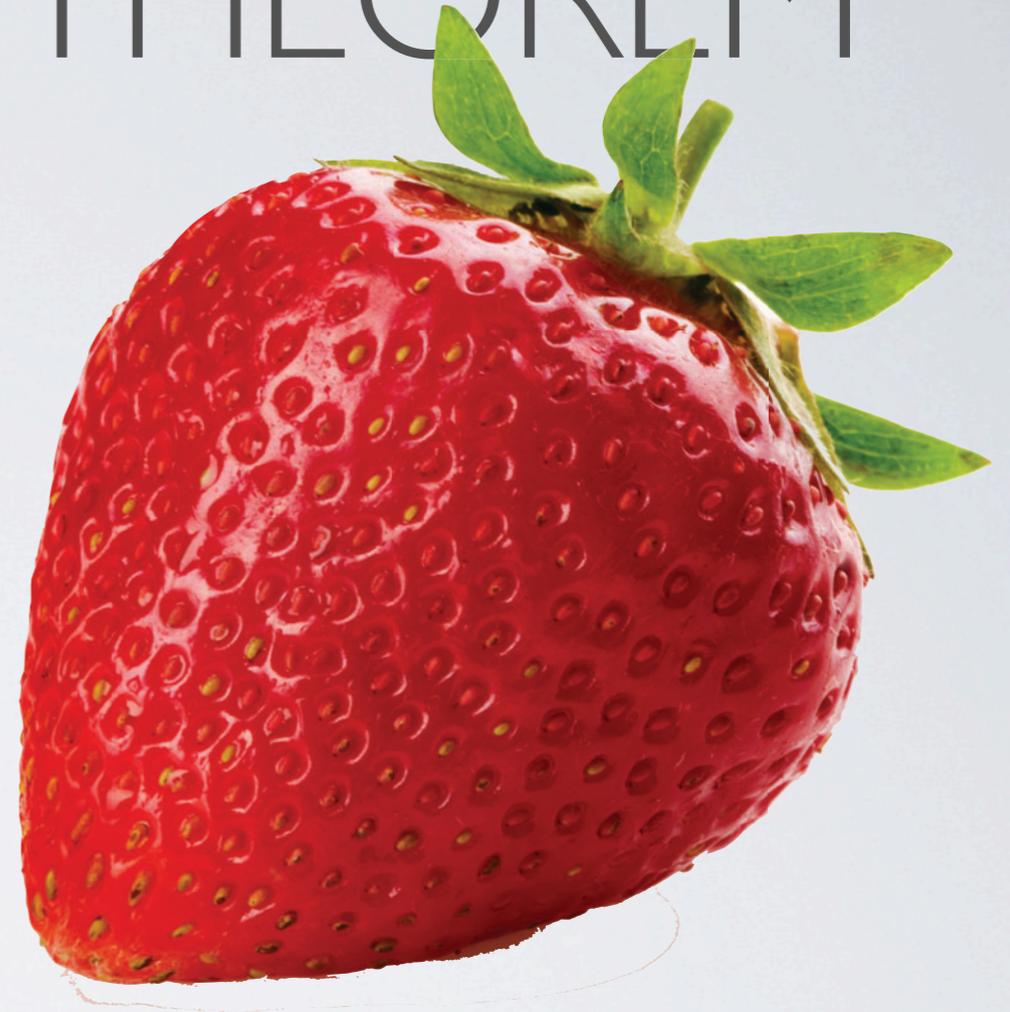

Critical points of the  
average cost are  
break even points.

# THE STRAWBERRY THEOREM

$$f = g \iff g' = 0$$

Proof?

PROOF:

$$g' = (F/x)' = F'/x - F/x^2 = 0$$

This means  $f_x = F$

# THE CARTOON INTRODUCTION TO ECONOMICS

VOLUME ONE: MICROECONOMICS

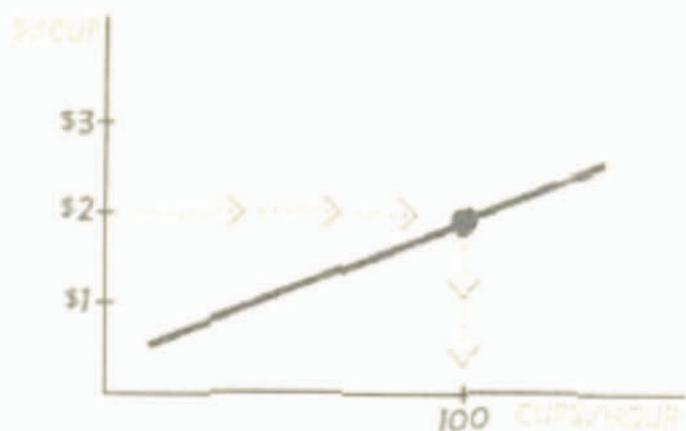

**BY GRADY KLEIN AND  
YORAM BAUMAN, Ph.D.**  
THE WORLD'S FIRST AND ONLY STAND-UP ECONOMIST

TO SEE HOW MARGINAL COST CURVES RELATE TO SUPPLY CURVES, LET'S LOOK AT ERNESTO'S COFFEE BUSINESS.

IT TURNS OUT THAT **EVERY POINT** ON ERNESTO'S **SUPPLY CURVE**...

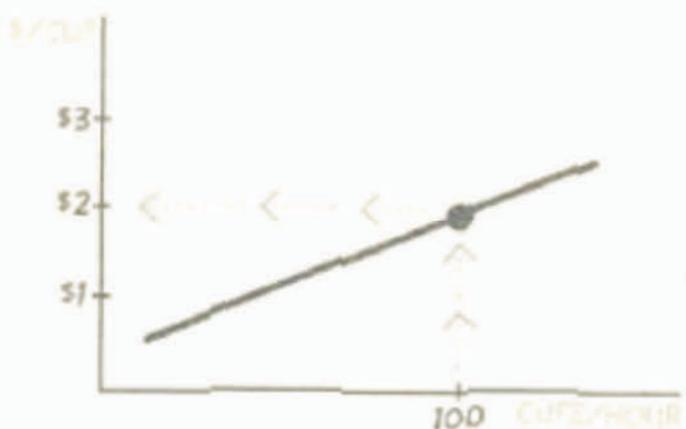

MY SUPPLY CURVE SAYS THAT IF THE MARKET PRICE WERE \$2 PER CUP,...

... I'D MAXIMIZE MY PROFIT BY SELLING 100 CUPS OF COFFEE PER HOUR.

... IS ALSO A POINT ON HIS MARGINAL COST CURVE!

THE MARGINAL COST OF PRODUCING THE 100TH CUP IS \$2,

THAT'S THE DIFFERENCE IN MY TOTAL COSTS BETWEEN PRODUCING 99 CUPS,...

... AND PRODUCING 100 CUPS!

THIS IS TRUE BECAUSE ERNESTO WANTS TO **MAXIMIZE HIS PROFIT.**

ERNESTO'S SUPPLY CURVE SAYS THAT IF THE MARKET PRICE WERE \$2 PER CUP, HE'D MAXIMIZE HIS PROFIT BY SELLING 100 CUPS.

BUT IF THE 100TH CUP COST MORE THAN \$2 TO PRODUCE,...

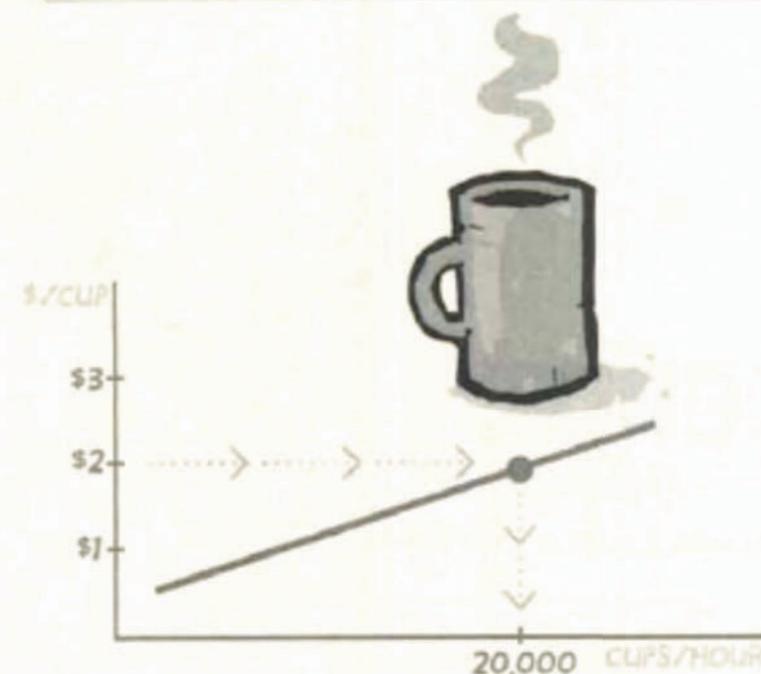

... I COULD MAKE MORE PROFIT BY SELLING FEWER THAN 100 CUPS

AND IF THE 100TH CUP COST LESS THAN \$2 TO PRODUCE,...

... I COULD MAKE MORE PROFIT BY SELLING MORE THAN 100 CUPS

IF WE LOOK AT ERNESTO AND ALL THE OTHER WE CAN SEE THAT **EVERY POINT ON THE MARKET MARGINAL** **A POINT ON THE MARKET MARGINAL**

IF THE MARKET SUPPLY CURVE SAYS THAT AT A PRICE OF \$2 ALL THE SELLERS TOGETHER WANT TO SELL 20,000 CUPS OF COFFEE PER HOUR,...

AGAIN, THE REASON IS **PROFIT**

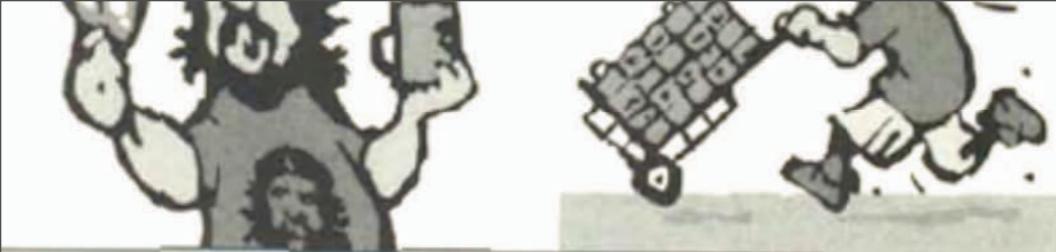

IF THE 20,000TH CUP COST MORE THAN \$2 TO PRODUCE,...

... AT LEAST ONE OF US COULD MAKE MORE PROFIT BY SELLING FEWER CUPS AT A MARKET PRICE OF \$2!

ALL THESE LOGICAL ARGUMENTS CAN BE BACKED UP

... BUT WE'D

ON HIS MARGINAL COST CURVE!

THE MARGINAL COST OF PRODUCING THE 100TH CUP IS \$2,

THAT'S THE DIFFERENCE IN MY TOTAL COSTS BETWEEN PRODUCING 99 CUPS...

... AND PRODUCING 100 CUPS!

BECAUSE ERNESTO WANTS TO MAXIMIZE HIS PROFIT,

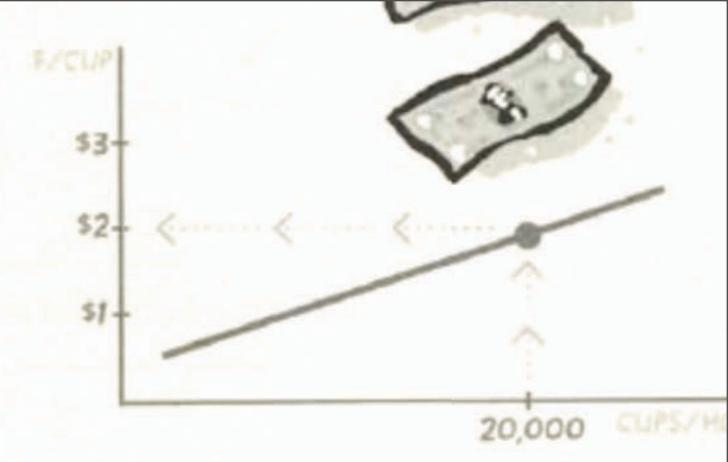

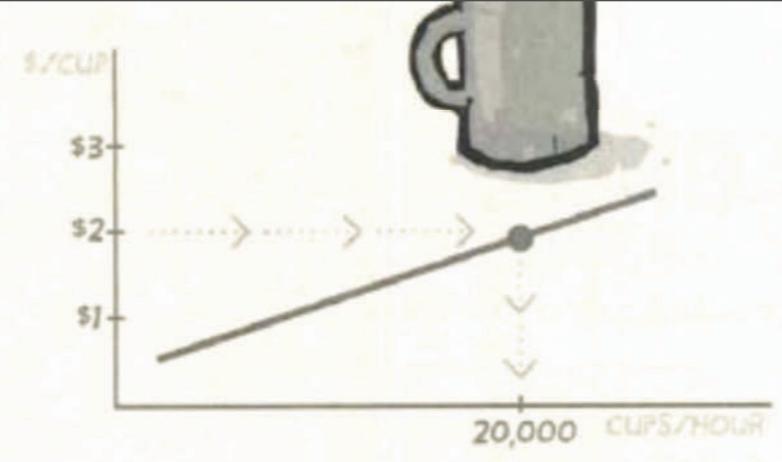

SAYS THAT IF THE MARKET PRICE WERE \$2 PER CUP, HE WOULD MAXIMIZE HIS PROFIT BY SELLING 100 CUPS.

AND IF THE 100TH CUP COST LESS THAN \$2 TO PRODUCE...

... I COULD MAKE MORE PROFIT BY SELLING MORE THAN 100 CUPS AT A MARKET PRICE OF \$2 PER CUP.

THE MARGINAL COST OF PRODUCING THE 100TH CUP MUST BE \$2.

AGAIN, THE REASON IS **PROFIT MAXIMIZATION**.

IF THE 20,000TH CUP COST MORE THAN \$2 TO PRODUCE...

... AT LEAST ONE OF US COULD MAKE MORE PROFIT BY SELLING FEWER CUPS AT A MARKET PRICE OF \$2!

AND IF THE 20,000TH CUP COST LESS THAN \$2 TO PRODUCE...

... AT LEAST ONE OF US COULD MAKE MORE PROFIT BY SELLING MORE CUPS AT A MARKET PRICE OF \$2!

ALL THESE LOGICAL ARGUMENTS CAN BE BACKED UP WITH **ROCK-SOLID MATHEMATICS**...

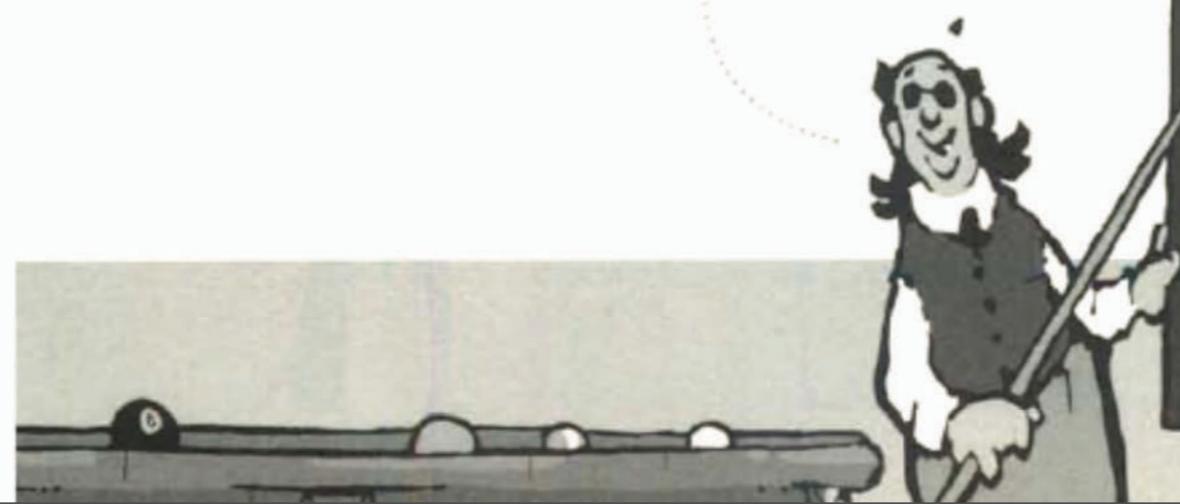

... BUT WE'D NEED TO DO SOME **CALCULUS**.

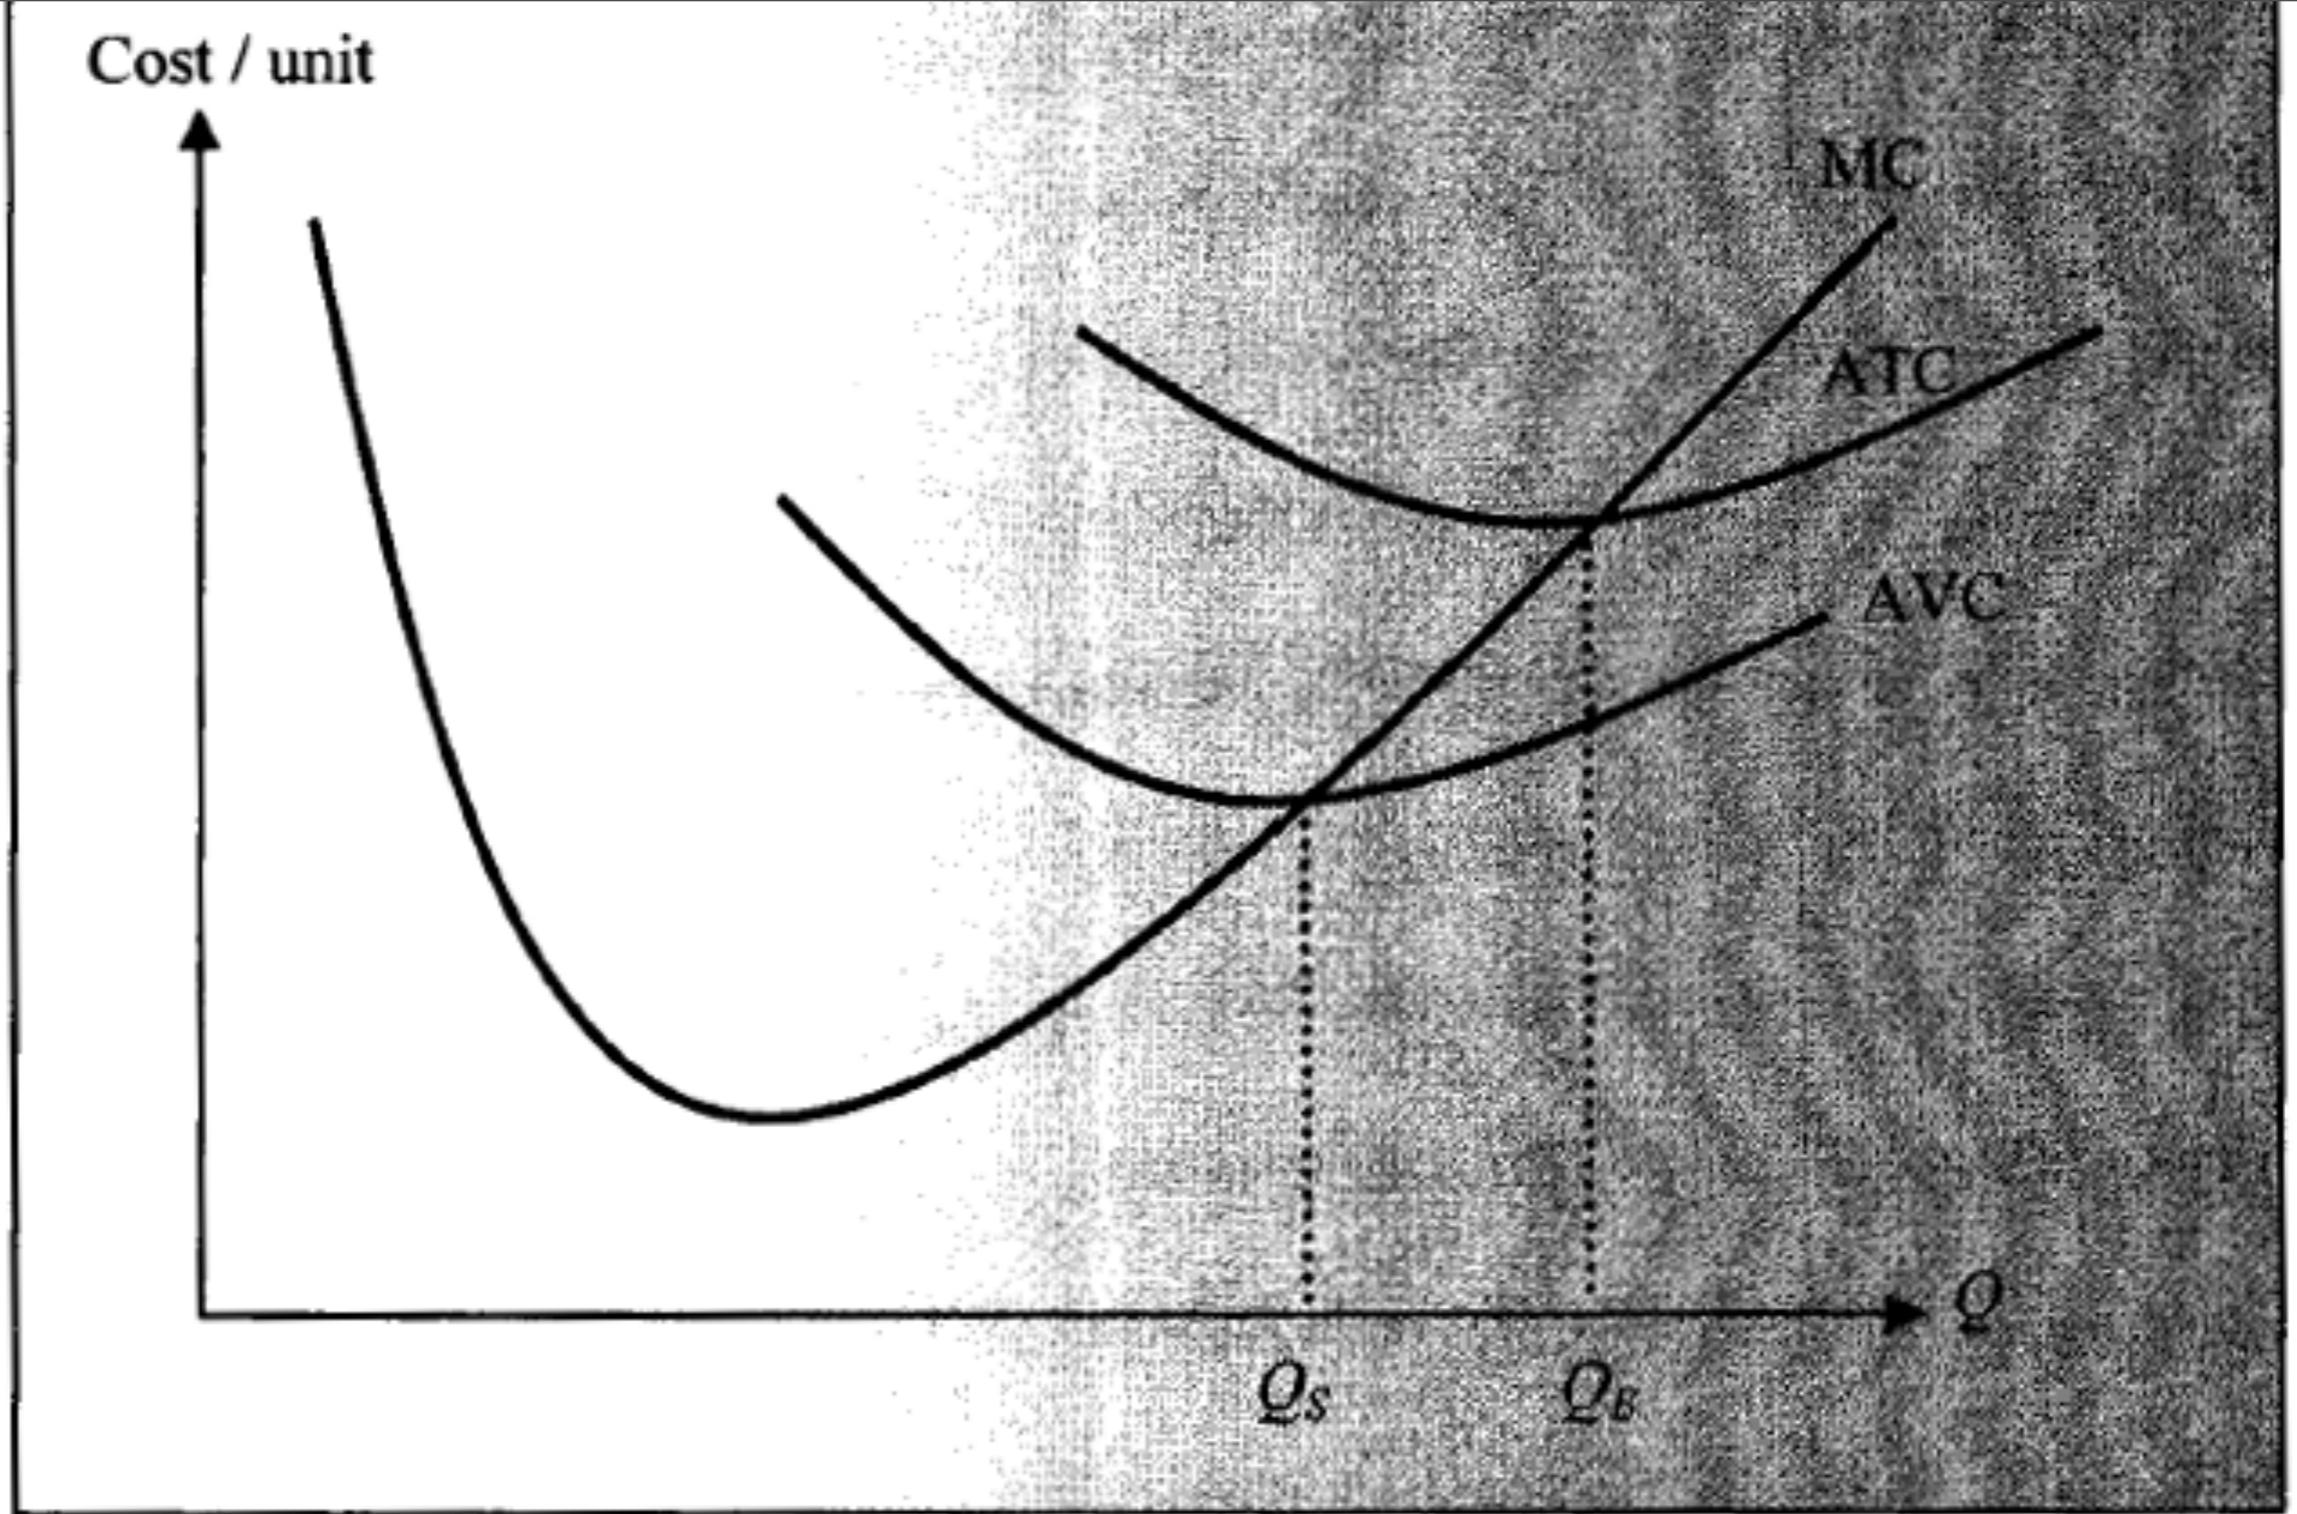

Facing market price  $p$ , a firm in a competitive market chooses quantity  $q$  to maximize profit  $\pi$ :

$$\pi = pq - c(q)$$

$$\frac{d\pi}{dq} = 0 \Rightarrow p = c'(q)$$

So either  $q=0$  or the firm produces until marginal cost equals the market price!

**Fig. 9.4.** The marginal cost MC curve cuts through average variable cost AVC and average total cost ATC curves at their respective minima. These points are the shutdown and break-even points, respectively

You take one strawberry after another and place them on a scale that tells you the average weight of all strawberries. The first strawberry that you

## Mathematical Proof

Rather than blindly trusting the intuition above, we can also prove our analysis mathematically. Let us perform this proof for the intersection of MC and ATC. Our first step is to compute the derivative of ATC with respect to  $Q$  and set this equal to zero to find the curve's critical point, here the minimum:

$$\frac{dATC}{dQ} = 0 \quad (9.14)$$

In order to make Equation 9.14 usable, let us substitute  $TC/Q$  for ATC. Therefore, we get:

$$\frac{d\left(\frac{TC}{Q}\right)}{dQ} = 0 \quad (9.15)$$

To avoid complicated calculus, let us reformulate the numerator as a product:

$$\frac{d(TC \cdot Q^{-1})}{dQ} = 0 \quad (9.16)$$

Remembering the **product rule**, we differentiate  $TC \cdot Q^{-1}$  with respect to

tion. When looking at Equation 9.17, we notice that the very first term is MC and so we can write:

$$MC \cdot Q^{-1} - TC \cdot Q^{-2} = 0 \quad (9.18)$$

As a final step we multiply both sides by  $Q$  and write the second term as a fraction:

$$MC - \frac{TC}{Q} = 0 \quad (9.19)$$

Since, by definition,  $TC/Q$  is equal to  $ATC$ , we finalise our equation to become:

$$MC - ATC = 0 \quad (9.20)$$

Now our task of proving that  $ATC$  is equal to  $MC$  when  $ATC$  is at its minimum is easy. Having taken the derivative of  $ATC$  in Equation 9.14 to show its minimum, we have worked all the way to Equation 9.20. This last Equation will hold true, i.e. will correspond to a minimum of the  $ATC$  curve when we set  $MC$  and  $ATC$  equal to each other. Hence, when  $MC$  is equal to  $ATC$ ,  $ATC$  is at its minimum. The same mathematical steps can be followed to prove the intersection of  $AVC$  and  $MC$  at the minimum of  $AVC$ .
