

Lecture 5: Functions

A **function of two variables** $f(x, y)$ is a rule which assigns to two numbers x, y a third number $f(x, y)$. For example, the function $f(x, y) = x^2y + 2x$ assigns to $(3, 2)$ the number $3^2 \cdot 2 + 6 = 24$.

A function is usually defined for all points (x, y) in the plane like for $f(x, y) = x^2 + \sin(xy)$. Sometimes, it is needed however to restrict the function to a **domain** D in the plane like for $f(x, y) = 1/y$, where (x, y) is defined everywhere except on the x -axis $y = 0$. The **range** of a function f is the set of values which the function f takes. The function $f(x, y) = 1 + x^2$ for example takes all values $z \geq 1$.

The **graph** of $f(x, y)$ is the set $\{(x, y, f(x, y)) \mid (x, y) \in D\}$ in space. Graphs allow to visualize functions of two variables and see the function.

- 1 The graph of $f(x, y) = \sqrt{1 - x^2 - y^2}$ on the domain $x^2 + y^2 < 1$ is a half sphere.

2

Example $f(x, y)$	domain D of f	range = $f(D)$ of f
$f(x, y) = \sin(3x + 3y) - \log(1 - x^2 - y^2)$	open unit disc $x^2 + y^2 < 1$	$[-1, \infty)$
$f(x, y) = f(x, y) = x^2 + y^3 - xy + \cos(xy)$	plane $\mathbb{R}^2$	the real line
$f(x, y) = \sqrt{4 - x^2 - 2y^2}$	$x^2 + 2y^2 \leq 4$	$[0, 2]$
$f(x, y) = 1/(x^2 + y^2 - 1)$	all except unit circle	the real line
$f(x, y) = 1/(x^2 + y^2)^2$	all except origin	positive real axis

The set $\{(x, y) \mid f(x, y) = c = \text{const}\}$ is called a **contour curve** or **level curve** of f . For example, for $f(x, y) = 4x^2 + 3y^2$, the level curves $f = c$ are ellipses if $c > 0$. Drawing several contour curves $\{f(x, y) = c\}$ produces a **contour map** of the function f .

Level curves allow to visualize functions of two variables $f(x, y)$ without leaving the plane. The picture to the right for example shows the level curves of the function $\sin(xy) - \sin(x^2 + y^2)$. Contour curves are encountered every day: they appear for example as **isobars**=curves of constant pressure, or **isoclines**= curves of constant (wind) field direction, **isothermes**= curves of constant temperature or **isoheights** =curves of constant height.

- 3 For $f(x, y) = x^2 - y^2$, the set $x^2 - y^2 = 0$ is the union of the lines $x = y$ and $x = -y$. The set $x^2 - y^2 = 1$ consists of two hyperbola with their "noses" at the point $(-1, 0)$ and $(1, 0)$. The set $x^2 - y^2 = -1$ consists of two hyperbola with their noses at $(0, 1)$ and $(0, -1)$.
- 4 The function $f(x, y) = 1 - 2x^2 - y^2$ has contour curves $f(x, y) = 1 - 2x^2 + y^2 = c$ which are ellipses $2x^2 + y^2 = 1 - c$ for $c < 1$.
- 5 For the function $f(x, y) = (x^2 - y^2)e^{-x^2 - y^2}$, we can not find explicit expressions for the contour curves $(x^2 - y^2)e^{-x^2 - y^2} = c$. We can draw the curves however with the help of a computer:

- 6 The surface $z = f(x, y) = \sin(\sqrt{x^2 + y^2})$ has concentric circles as contour curves.

In applications, we sometimes have to deal with functions which are not continuous. When plotting the rate of change of temperature of water in relation to pressure and volume for example, one experiences **phase transitions**, places where the function value can jump. Mathematicians have tamed singularities in a mathematical field called "catastrophe theory".

A function $f(x, y)$ is called **continuous** at (a, b) if $f(a, b)$ is finite and $\lim_{(x, y) \rightarrow (a, b)} f(x, y) = f(a, b)$. This means that for any sequence (x_n, y_n) converging to (a, b) , also $f(x_n, y_n) \rightarrow f(a, b)$.

Continuity means that if (x, y) is close to (a, b) , then $f(x, y)$ is close to $f(a, b)$. Continuity for functions of more than two variables is defined in the same way. Continuity is not always easy to check. Fortunately however, we do not have to worry about it most of the time. Lets look at some examples:

7 Example: For $f(x, y) = (xy)/(x^2 + y^2)$, we have $\lim_{(x, x) \rightarrow (0, 0)} f(x, x) = \lim_{x \rightarrow 0} x^2/(2x^2) = 1/2$ and $\lim_{(x, 0) \rightarrow (0, 0)} f(0, x) = \lim_{(x, 0) \rightarrow (0, 0)} 0 = 0$. The function is not continuous.

8 For $f(x, y) = (x^2y)/(x^2 + y^2)$, it is better to describe the function using polar coordinates: $f(r, \theta) = r^3 \cos^2(\theta) \sin(\theta)/r^2 = r \cos^2(\theta) \sin(\theta)$. We see that $f(r, \theta) \rightarrow 0$ uniformly if $r \rightarrow 0$. The function is continuous.

A function of three variables $g(x, y, z)$ assigns to three variables x, y, z a real number $g(x, y, z)$. We can visualize it by **contour surfaces** $g(x, y, z) = c$, where c is constant. To understand a contour surface, it is helpful to look at the **traces**, the intersections of the surfaces with the coordinate planes $x = 0, y = 0$ or $z = 0$.

Many surfaces can be described as level surfaces. If this is the case, we call this an **implicit description** of a surface. Here are some examples we know already:

- 9 The function $g(x, y, z) = 2 + \sin(xyz)$ could define a temperature distribution in space. We can no more draw a graph of g because that would be an object in 4 dimensions. We can however draw surfaces like $g(x, y, z) = 0$.
- 10 The level surfaces of $g(x, y, z) = x^2 + y^2 + z^2$ are spheres. The level surfaces of $g(x, y, z) = 2x^2 + y^2 + 3z^2$ are ellipsoids.
- 11 For $g(x, y, z) = z - f(x, y)$, the level surface $g = 0$ agrees with the graph $z = f(x, y)$ of f . For example, for $g(x, y, z) = z - x^2 - y^2 = 0$, the graph $z = x^2 + y^2$ of the function $f(x, y) = x^2 + y^2$ is a paraboloid. Graphs are special surfaces. Most surfaces of the form $g(x, y, z) = c$ can not be written as graphs. The sphere is an example. We would need two graphs to cover it.
- 12 The equation $ax + by + cz = d$ is a plane. With $\vec{n} = \langle a, b, c \rangle$ and $\vec{x} = \langle x, y, z \rangle$, we can rewrite the equation $\vec{n} \cdot \vec{x} = d$. If a point $\vec{x}_0$ is on the plane, then $\vec{n} \cdot \vec{x}_0 = d$. so that $\vec{n} \cdot (\vec{x} - \vec{x}_0) = 0$. This means that every vector $\vec{x} - \vec{x}_0$ in the plane is orthogonal to $\vec{n}$.
- 13 For $f(x, y, z) = ax^2 + by^2 + cz^2 + dxy + exz + fyz + gx + hy + kz + m$ the surface $f(x, y, z) = 0$ is called a **quadric**. We will look at a few examples.

Sphere

Paraboloid

Plane

$$(x-a)^2 + (y-b)^2 + (z-c)^2 = r^2 \quad (x-a)^2 + (y-b)^2 - c = z$$

$$ax + by + cz = d$$

One sheeted Hyperboloid

Cylinder

Two sheeted Hyperboloid

$$(x-a)^2 + (y-b)^2 - (z-c)^2 = r^2$$

$$(x-a)^2 + (y-b)^2 = r^2$$

$$(x-a)^2 + (y-b)^2 - (z-c)^2 = -r^2$$

Ellipsoid

Hyperbolic paraboloid

Elliptic hyperboloid

$$x^2/a^2 + y^2/b^2 + z^2/c^2 = 1$$

$$x^2 - y^2 + z = 1$$

$$x^2/a^2 + y^2/b^2 - z^2/c^2 = 1$$

- 14 Higher order polynomial surfaces can be intriguingly beautiful and difficult to describe. If f is a polynomial in several variables and $f(x, x, x)$ is a polynomial of degree d , then f is called a **degree d polynomial surface**. Degree 2 surfaces are **quadrics**, degree 3 surfaces **cubics**, degree 4 surfaces **quartics**, degree 5 surfaces **quintics**, degree 10 surfaces **decics** and so on.

Homework

- 1 Determine the domain and range from the following function

$$\log(1 + x^2 - y^2)$$

and then sketch the graph. We always denote by $\log$ the natural log.

- 2 Consider the surface $z^2 - 4z + x^2 - 2x - y = 0$. Draw the three traces, intersections with the coordinate planes. Do you recognize the surface?

- 3 Use online tools or your computer to draw the level surface $x^2 + y^2 - xyz = 1$ and its traces.

- 4 a) Sketch the graph and contour map of the function $f(x, y) = \sin(x^2 + y^2)/(1 + x^2 + y^2)$.
b) Sketch the graph and contour map of the function $g(x, y) = |x| - |y|$.

- 5 Verify that the line $\vec{r}(t) = \langle 1, 3, 2 \rangle + t\langle 1, 2, 1 \rangle$ is contained in the surface $z^2 - x^2 - y = 0$.

Lecture 6: Parametrized surfaces

There is a second, fundamentally different way to describe a surface, the **parametrization**.

A **parametrization** of a surface is a vector-valued function

$$\vec{r}(u, v) = \langle x(u, v), y(u, v), z(u, v) \rangle ,$$

where $x(u, v), y(u, v), z(u, v)$ are three functions of two variables.

Because two parameters u and v are involved, the map $\vec{r}$ is also called **uv-map**.

A **parametrized surface** is the image of the uv-map. The domain of the uv-map is called the **parameter domain**.

If we keep the first parameter u constant, then $v \mapsto \vec{r}(u, v)$ is a curve on the surface. Similarly, if v is constant, then $u \mapsto \vec{r}(u, v)$ traces a curve the surface. These curves are called **grid curves**.

A computer draws surfaces using grid curves. The world of parametric surfaces is intriguing and complex. You can explore this world with the help of the computer algebra system Mathematica. You can survive the parametrization of surfaces topic by keeping in mind 4 important examples. They are *really important* because they: are cases we can understand well and which consequently will return again and again.

1 Planes. Parametric: $\vec{r}(s, t) = \vec{OP} + s\vec{v} + t\vec{w}$

Implicit: $ax + by + cz = d$. Parametric to Implicit: find the normal vector $\vec{n} = \vec{v} \times \vec{w}$.

Implicit to Parametric: find two vectors $\vec{v}, \vec{w}$ normal to the vector $\vec{n}$. For example, find three points P, Q, R on the surface and forming $\vec{u} = \vec{PQ}, \vec{v} = \vec{PR}$.

- 2 Spheres:** Parametric: $\vec{r}(u, v) = \langle a, b, c \rangle + \langle \rho \cos(u) \sin(v), \rho \sin(u) \sin(v), \rho \cos(v) \rangle$.
 Implicit: $(x - a)^2 + (y - b)^2 + (z - c)^2 = \rho^2$.
 Parametric to implicit: reading off the radius.
 Implicit to parametric: find the center (a, b, c) and the radius r possibly by completing the square.

- 3 Graphs:**
 Parametric: $\vec{r}(u, v) = \langle u, v, f(u, v) \rangle$
 Implicit: $z - f(x, y) = 0$. Parametric to Implicit: think about $z = f(x, y)$
 Implicit to Parametric: use x and y as the parameterizations.

- 4 Surfaces of revolution:**
 Parametric: $r(u, v) = (g(v) \cos(u), g(v) \sin(u), v)$
 Implicit: $\sqrt{x^2 + y^2} = r = g(z)$ can be written as $x^2 + y^2 = g(z)^2$.
 Parametric to Implicit: read off the function $g(z)$ the distance to the z -axis.
 Implicit to Parametric: use the function g .

A point (x, y) in the plane has the **polar coordinates** $r = \sqrt{x^2 + y^2}, \theta = \arctg(y/x)$. We have $(x, y) = (r \cos(\theta), r \sin(\theta))$.

The formula $\theta = \arctg(y/x)$ defines the angle θ only up to an addition of π . The points (x, y) and $(-x, -y)$ have the same θ value. In order to get the correct θ , one can take $\arctan(y/x)$ in $(-\pi/2, \pi/2]$, where $\pi/2$ is the limit when $x \rightarrow 0^+$, then add π if $x < 0$ or $x = 0, y < 0$.

If we represent points in space as

$$(x, y, z) = (r \cos(\theta), r \sin(\theta), z)$$

we speak of **cylindrical coordinates**.

Here are some level surfaces in cylindrical coordinates:

- 5 $r = 1$ is a **cylinder**, $r = |z|$ is a **double cone** $\theta = 0$ is a **half plane** $r = \theta$ is a **rolled sheet of paper**
- 6 $r = 2 + \sin(z)$ is an example of a **surface of revolution**.

Spherical coordinates use the distance ρ to the origin as well as two angles θ and ϕ . The first angle θ is the polar angle in polar coordinates of the first two coordinates and ϕ is the angle between the vector $\vec{OP}$ and the z -axis. A point has the **spherical coordinate**

$$(x, y, z) = (\rho \cos(\theta) \sin(\phi), \rho \sin(\theta) \sin(\phi), \rho \cos(\phi)) .$$

There are two important figures. The distance to the z axes $r = \rho \sin(\phi)$ and the height $z = \rho \cos(\phi)$ can be read off by the left picture, the coordinates $x = r \cos(\theta), y = r \sin(\theta)$ can be seen in the right picture.

$$\begin{aligned} x &= \rho \cos(\theta) \sin(\phi), \\ y &= \rho \sin(\theta) \sin(\phi), \\ z &= \rho \cos(\phi) \end{aligned}$$

Here are some level surfaces described in spherical coordinates:

- 7 $\rho = 1$ is a **sphere**, the surface $\phi = \pi/2$ is a **single cone**, $\rho = \phi$ is an **apple shaped surface** and $\rho = 2 + \cos(3\theta) \sin(\phi)$ is an example of a **bumpy sphere**.

Homework

- 1 Plot the surface with the parametrization

$$\vec{r}(u, v) = \langle \cos^2(v) \cos(u), \cos^2(v) \sin(u), v \rangle ,$$

where $u \in [0, 2\pi]$ and $v \in \mathbf{R}$.

- 2 Find a parametrization for the plane which contains the three points $P = (3, 7, 1)$, $Q = (1, 2, 1)$ and $R = (0, 3, 4)$.

- 3 a) Find a parametrizations of the lower half of the ellipsoid $9x^2 + 4y^2 + z^2 = 1, z < 0$ by using that the surface is a graph $z = f(x, y)$.

b) Find a second parametrization but use angles ϕ, θ similarly as for the sphere.

- 4 Find a parametrisation of the **torus**, the set of points which have distance 1 from the circle $\langle 2 \cos(\theta), 2 \sin(\theta), 0 \rangle$, where θ is the angle occuring in cylindrical and spherical coordinates.

Hint: Keep $u = t$ as one of the parameters and let r the distance of a point on the torus to the z -axis. This distance is $r = 2 + \cos(\phi)$ if ϕ is the angle you see on Figure 1. You can read off from the same picture also $z = \sin(\phi)$. To finish the parametrization problem, you have to translate back from cylindrical coordinates $(r, \theta, z) = (2 + \cos(\phi), \theta, \sin(\phi))$ to Cartesian coordinates (x, y, z) .

- 5 a) What is the equation for the surface $x^2 + y^2 - 10x = z^2$ in cylindrical coordinates?
- b) Describe in words or draw a sketch of the surface whose equation is $\rho = |\sin(3\phi)|$ in spherical coordinates (ρ, θ, ϕ) .

Lecture 7: Parametrized curves

A **parametrization** of a curve is a map $\vec{r}(t) = \langle x(t), y(t) \rangle$ from a **parameter interval** $R = [a, b]$ to the plane. The functions $x(t), y(t)$ are called **coordinate functions**. The image of the parametrization is called a **parametrized curve** in the plane. In three dimensions, the parametrization is $\vec{r}(t) = \langle x(t), y(t), z(t) \rangle$ and the image of r is a **parametrized curve** in space.

We always think of the **parameter** t as **time**. For a fixed time t , we have a vector $\langle x(t), y(t), z(t) \rangle$ in space. As t varies, the end point of this vector moves along the curve. The parametrization contains more information about the curve than the curve alone. It tells for example, how fast we go along the curve.

- 1) The parametrization $\vec{r}(t) = \langle \cos(3t), \sin(5t) \rangle$ describes a curve in the plane. It is an example of a **Lissajous curve**.
- 2) If $x(t) = t$, $y(t) = f(t)$, the curve $\vec{r}(t) = \langle t, f(t) \rangle$ traces the **graph** of the function $f(x)$. For example, for $f(x) = x^2 + 1$, the graph is a parabola.
- 3) With $x(t) = 2 \cos(t)$, $y(t) = \sin(t)$, then $\vec{r}(t)$ follows an **ellipse**. We can see this from $x(t)^2/4 + y(t)^2 = 1$. We can overlay another circular motion to get an epicycle $\vec{r}(t) = \langle \cos(t) + \cos(31t)/4, 4 \sin(t) + \sin(31t)/4 \rangle$.
- 4) With $x(t) = t \cos(t)$, $y(t) = t \sin(t)$, $z(t) = t$ we get the parametrization of a **space curve** $\vec{r}(t) = \langle t \cos(t), t \sin(t), t \rangle$. It traces a **helix** which has a radius changing linearly.
- 5) If $x(t) = \cos(2t)$, $y(t) = \sin(2t)$, $z(t) = 2t$, then we have the same curve as in the previous example but the curve is traversed **faster**. The **parameterization** of the curve has changed.
- 6) If $x(t) = \cos(-t)$, $y(t) = \sin(-t)$, $z(t) = -t$, then we have the same curve again but we traverse it in the **opposite direction**.

- 7 If $P = (a, b, c)$ and $Q = (u, v, w)$ are points in space, then $\vec{r}(t) = \langle a + t(u - a), b + t(v - b), c + t(w - c) \rangle$ defined on $t \in [0, 1]$ is a **line segment** connecting P with Q . For example, $\vec{r}(t) = \langle 1 + t, 1 - t, 2 + 3t \rangle$ connects the points $P = (1, 1, 2)$ with $Q = (2, 0, 1)$.

Sometimes it is possible to eliminate the time parameter t and write the curve using equations. We need one equation to do so in two dimensions and two equations in three dimensions.

Some curves can be written as the intersection of two surfaces. The pair of equations $f(x, y, z) = 0, g(x, y, z) = 0$ is called an implicit description of a curve.

- 8 The symmetric equations describing a line $(x - x_0)/a = (y - y_0)/b = (z - z_0)/c$ can be seen as the intersection of two surfaces.
- 9 If f and g are polynomials, the set of points satisfying $f(x, y, z) = 0, g(x, y, z) = 0$ is an example of an **algebraic variety**. An example is the set of points in space satisfying $x^2 - y^2 + z^3 = 0, x^5 - y + z^5 + xy = 3$. An other example is the set of points satisfying $x^2 + 4y^2 = 5, x + y + z = 1$ which is an ellipse in space.
- 10 For $x(t) = t \cos(t), y(t) = t \sin(t), z(t) = t$, then $x = t \cos(z), y = t \sin(z)$ and we can see that $x^2 + y^2 = z^2$. The curve is located on a cone. We also have $x/y = \tan(z)$ so that we could see the curve as an intersection of two surfaces. Detecting relations between x, y, z can help to understand the curve.
- 11 Curves describe the paths of particles, celestial bodies, or quantities which change in time. Examples are the motion of a star moving in a galaxy, or economical data changing in time.. Here are some more places, where curves appear:

Strings or knots	are closed curves in space.
Large Molecules	like RNA or proteins can be modeled as curves.
Computer graphics:	surfaces are represented by mesh of curves.
Typography:	fonts represented by Bezier curves.
Space time:	curve in space-time describes the motion of an object
Topology:	space filling curves, boundaries of surfaces or knots.

If $\vec{r}(t) = \langle x(t), y(t), z(t) \rangle$ is a curve, then $\vec{r}'(t) = \langle x'(t), y'(t), z'(t) \rangle = \langle \dot{x}, \dot{y}, \dot{z} \rangle$ is called the **velocity** at time t . Its length $|\vec{r}'(t)|$ is called **speed** and $\vec{v}/|\vec{v}|$ is called **direction of motion**. The vector $\vec{r}''(t)$ is called the **acceleration**. The third derivative $\vec{r}'''$ is called the **jerk**.

Any vector parallel to the velocity vector $\vec{r}'(t)$ is called **tangent** to the curve at $\vec{r}(t)$.

Here are where velocities, acceleration and jerk are computed:

$$\begin{array}{lll} \text{Position} & \vec{r}(t) & = \langle \cos(3t), \sin(2t), 2\sin(t) \rangle \\ \text{Velocity} & \vec{r}'(t) & = \langle -3\sin(3t), 2\cos(2t), 2\cos(t) \rangle \\ \text{Acceleration} & \vec{r}''(t) & = \langle -9\cos(3t), -4\sin(2t), -2\sin(t) \rangle \\ \text{Jerk} & \vec{r}'''(t) & = \langle 27\sin(3t), 8\cos(2t), -2\cos(t) \rangle \end{array}$$

Lets look at some examples of velocities and accelerations:

Signals in nerves:	40 m/s	Train:	0.1-0.3 m/s^2
Plane:	70-900 m/s	Car:	3-8 m/s^2
Sound in air:	Mach 1=340 m/s	Free fall:	1G = 9.81 m/s^2
Speed of bullet:	1200-1500 m/s	Space shuttle:	3G = 30 m/s^2
Earth around the sun:	30'000 m/s	Combat plane F16:	9G m/s^2
Sun around galaxy center:	200'000 m/s	Ejection from F16:	14G m/s^2 .
Light in vacuum:	300'000'000 m/s	Electron in vacuum tube:	$10^{15} m/s^2$

The **addition rule** in one dimension $(f+g)' = f' + g'$, the **scalar multiplication rule** $(cf)' = cf'$ and the **Leibniz rule** $(fg)' = f'g + fg'$ and the **chain rule** $(f(g))' = f'(g)g'$ generalize to vector-valued functions because in each component, we have the single variable rule.

$$(\vec{v} + \vec{w})' = \vec{v}' + \vec{w}', (c\vec{v})' = c\vec{v}', (\vec{v} \cdot \vec{w})' = \vec{v}' \cdot \vec{w} + \vec{v} \cdot \vec{w}' \quad (\vec{v} \times \vec{w})' = \vec{v}' \times \vec{w} + \vec{v} \times \vec{w}'$$

$$(\vec{v}(f(t)))' = \vec{v}'(f(t))f'(t).$$

The process of differentiation of a curve can be reversed using the **fundamental theorem of calculus**. If $\vec{r}'(t)$ and $\vec{r}(0)$ is known, we can figure out $\vec{r}(t)$ by **integration** $\vec{r}(t) = \vec{r}(0) + \int_0^t \vec{r}'(s) ds$.

Assume we know the acceleration $\vec{a}(t) = \vec{r}''(t)$ at all times as well as initial velocity and position $\vec{r}'(0)$ and $\vec{r}(0)$. Then $\vec{r}(t) = \vec{r}(0) + t\vec{r}'(0) + \vec{R}(t)$, where $\vec{R}(t) = \int_0^t \vec{v}(s) ds$ and $\vec{v}(t) = \int_0^t \vec{a}(s) ds$.

The **free fall** is the case when acceleration is constant. The direction of the constant force defines what is "down". If $\vec{r}''(t) = \langle 0, 0, -10 \rangle$, $\vec{r}'(0) = \langle 0, 1000, 2 \rangle$, $\vec{r}(0) = \langle 0, 0, h \rangle$, then $\vec{r}(t) = \langle 0, 1000t, h + 2t - 10t^2/2 \rangle$.

If $\vec{r}''(t) = \vec{F}$ is constant, then $\vec{r}(t) = \vec{r}(0) + t\vec{r}'(0) - \vec{F}t^2/2$.

Homework

- 1 Sketch the plane curve $\vec{r}(t) = \langle x(t), y(t) \rangle = \langle t^3, t^2 \rangle$ for $t \in [-1, 1]$ by plotting the points for different values of t . Calculate its velocity $\vec{r}'(t)$ as well as its acceleration $\vec{r}''(t)$ at the point $t = 2$.
- 2 A device in a car measures the acceleration $\vec{r}''(t) = \langle \cos(t), -\cos(3t) \rangle$ at time t . Assume that the car is at the origin $(0, 0)$ at time $t = 0$ and has zero speed at $t = 0$, what is its position $\vec{r}(t)$ at time t ?
- 3 Verify that the curve $\vec{r}(t) = \langle t \cos(t), 2t \sin(t), t^2 \rangle$ is located on the **elliptical paraboloid**

$$z = x^2 + \frac{y^2}{4} .$$

Use this fact to sketch the curve.

- 4 Find the parameterization $\vec{r}(t) = \langle x(t), y(t), z(t) \rangle$ of the curve obtained by intersecting the elliptical cylinder $x^2/9 + y^2/25 = 1$ with the surface $z = xy$. Find the velocity vector $\vec{r}'(t)$ at the time $t = \pi/2$.
- 5 Consider the curve

$$\vec{r}(t) = \langle x(t), y(t), z(t) \rangle = \langle t^2, 1 + t, 1 + t^3 \rangle .$$

Check that it passes through the point $(1, 0, 0)$ and find the velocity vector $\vec{r}'(t)$, the acceleration vector $\vec{r}''(t)$ as well as the jerk vector $\vec{r}'''(t)$ at this point.

Lecture 8: Arc length and curvature

If $t \in [a, b] \mapsto \vec{r}(t)$ is a curve with velocity $\vec{r}'(t)$ and speed $|\vec{r}'(t)|$, then $L = \int_a^b |\vec{r}'(t)| dt$ is called the **arc length** of the curve.

In space, we have $L = \int_a^b \sqrt{x'(t)^2 + y'(t)^2 + z'(t)^2} dt$.

1 The arc length of the **circle** of radius R given by $\vec{r}(t) = \langle R \cos(t), R \sin(t) \rangle$ parameterized by $0 \leq t \leq 2\pi$ is 2π because the speed $|\vec{r}'(t)|$ is constant and equal to R . The answer is $2\pi R$.

2 The **helix** $\vec{r}(t) = \langle \cos(t), \sin(t), t \rangle$ has velocity $\vec{r}'(t) = \langle -\sin(t), \cos(t), 1 \rangle$ and constant speed $|\vec{r}'(t)| = |\langle -\sin(t), \cos(t), 1 \rangle| = \sqrt{2}$.

3 What is the arc length of the curve

$$\vec{r}(t) = \langle t, \log(t), t^2/2 \rangle$$

for $1 \leq t \leq 2$? Answer: Because $\vec{r}'(t) = \langle 1, 1/t, t \rangle$, we have $|\vec{r}'(t)| = \sqrt{1 + \frac{1}{t^2} + t^2} = |\frac{1}{t} + t|$ and $L = \int_1^2 \frac{1}{t} + t dt = \log(t) + \frac{t^2}{2} \Big|_1^2 = \log(2) + 2 - 1/2$. This curve does not have a name. But because it is constructed in such a way that the arc length can be computed, we can call it "opportunity".

4 Find the arc length of the curve $\vec{r}(t) = \langle 3t^2, 6t, t^3 \rangle$ from $t = 1$ to $t = 3$.

5 What is the arc length of the curve $\vec{r}(t) = \langle \cos^3(t), \sin^3(t) \rangle$? Answer: We have $|\vec{r}'(t)| = 3\sqrt{\sin^2(t) \cos^4(t) + \cos^2(t) \sin^4(t)} = (3/2)|\sin(2t)|$. Therefore, $\int_0^{2\pi} (3/2) \sin(2t) dt = 6$.

6 Find the arc length of $\vec{r}(t) = \langle t^2/2, t^3/3 \rangle$ for $-1 \leq t \leq 1$. This cubic curve satisfies $y^2 = x^3/8$ and is an example of an **elliptic curve**. Because $\int x\sqrt{1+x^2} dx = (1+x^2)^{3/2}/3$, the integral can be evaluated as $\int_{-1}^1 |x|\sqrt{1+x^2} dx = 2 \int_0^1 x\sqrt{1+x^2} dx = 2(1+x^2)^{3/2}/3 \Big|_0^1 = 2(2\sqrt{2}-1)/3$.

7 The arc length of an **epicycle** $\vec{r}(t) = \langle t + \sin(t), \cos(t) \rangle$ parameterized by $0 \leq t \leq 2\pi$. We have $|\vec{r}'(t)| = \sqrt{2 + 2\cos(t)}$, so that $L = \int_0^{2\pi} \sqrt{2 + 2\cos(t)} dt$. A **substitution** $t = 2u$ gives $L = \int_0^\pi \sqrt{2 + 2\cos(2u)} 2du = \int_0^\pi \sqrt{2 + 2\cos^2(u) - 2\sin^2(u)} 2du = \int_0^\pi \sqrt{4\cos^2(u)} 2du = 4 \int_0^\pi |\cos(u)| du = 8$.

8 The arc length of the **catenary** $\vec{r}(t) = \langle t, \cosh(t) \rangle$, where $\cosh(t) = (e^t + e^{-t})/2$ is the **hyperbolic cosine** and $t \in [-1, 1]$. We have

$$\cosh^2(t) - \sinh^2(t) = 1,$$

where $\sinh(t) = (e^t - e^{-t})/2$ is the **hyperbolic sine**.

Because a parameter change $t = t(s)$ corresponds to a **substitution** in the integration which does not change the integral, we immediately have

The arc length is independent of the parameterization of the curve.

9 The circle parameterized by $\vec{r}(t) = \langle \cos(t^2), \sin(t^2) \rangle$ on $t = [0, \sqrt{2\pi}]$ has the velocity $\vec{r}'(t) = 2t\langle -\sin(t), \cos(t) \rangle$ and speed $2t$. The arc length is still $\int_0^{\sqrt{2\pi}} 2t \, dt = t^2 \Big|_0^{\sqrt{2\pi}} = 2\pi$.

10 Often, there is no closed formula for the arc length of a curve. For example, the **Lissajous figure** $\vec{r}(t) = \langle \cos(3t), \sin(5t) \rangle$ leads to the arc length integral $\int_0^{2\pi} \sqrt{9\sin^2(3t) + 25\cos^2(5t)} \, dt$ which can only be evaluated numerically.

Define the **unit tangent vector** $\vec{T}(t) = \vec{r}'(t)/|\vec{r}'(t)|$ **unit tangent vector**.

The **curvature** of a curve at the point $\vec{r}(t)$ is defined as $\kappa(t) = \frac{|\vec{T}'(t)|}{|\vec{r}'(t)|}$.

The curvature is the length of the acceleration vector if $\vec{r}(t)$ traces the curve with constant speed 1. A large curvature at a point means that the curve is strongly bent. Unlike the acceleration or the velocity, the curvature does not depend on the parameterization of the curve. You "see" the curvature, while you "feel" the acceleration.

The curvature does not depend on the parametrization.

Proof. Let $s(t)$ be an other parametrization, then by the chain rule $d/dtT'(s(t)) = T'(s(t))s'(t)$ and $d/dtr(s(t)) = r'(s(t))s'(t)$. We see that the s' cancels in T'/r' .

Especially, if the curve is parametrized by arc length, meaning that the velocity vector $r'(t)$ has length 1, then $\kappa(t) = |T'(t)|$. It measures the rate of change of the unit tangent vector.

11 The curve $\vec{r}(t) = \langle t, f(t) \rangle$, which is the graph of a function f has the velocity $\vec{r}'(t) = (1, f'(t))$ and the unit tangent vector $\vec{T}(t) = (1, f'(t))/\sqrt{1 + f'(t)^2}$. After some simplification we get

$$\kappa(t) = |\vec{T}'(t)|/|\vec{r}'(t)| = |f''(t)|/\sqrt{1 + f'(t)^2}^3$$

For example, for $f(t) = \sin(t)$, then $\kappa(t) = |\sin(t)|/\sqrt{1 + \cos^2(t)}^3$.

If $\vec{r}(t)$ is a curve which has nonzero speed at t , then we can define $\vec{T}(t) = \frac{\vec{r}'(t)}{|\vec{r}'(t)|}$, the **unit tangent vector**, $\vec{N}(t) = \frac{\vec{T}'(t)}{|\vec{T}'(t)|}$, the **normal vector** and $\vec{B}(t) = \vec{T}(t) \times \vec{N}(t)$ the **bi-normal vector**. The plane spanned by N and B is called the **normal plane**. It is perpendicular to the curve. The plane spanned by T and N is called the **osculating plane**.

If we differentiate $\vec{T}(t) \cdot \vec{T}(t) = 1$, we get $\vec{T}'(t) \cdot \vec{T}(t) = 0$ and see that $\vec{N}(t)$ is perpendicular to $\vec{T}(t)$. Because B is automatically normal to T and N , we have shown:

The three vectors $(\vec{T}(t), \vec{N}(t), \vec{B}(t))$ are unit vectors orthogonal to each other.

Here is an application of curvature: If a curve $\vec{r}(t)$ represents a **wave front** and $\vec{n}(t)$ is a **unit vector normal** to the curve at $\vec{r}(t)$, then $\vec{s}(t) = \vec{r}(t) + \vec{n}(t)/\kappa(t)$ defines a new curve called the **caustic** of the curve. Geometers call that curve the **evolute** of the original curve.

A useful formula for curvature is

$$\kappa(t) = \frac{|\vec{r}'(t) \times \vec{r}''(t)|}{|\vec{r}'(t)|^3}$$

We prove this in class. Finally, let's mention that curvature is important also in **computer vision**. If the gray level value of a picture is modeled as a function $f(x, y)$ of two variables, places where the level curves of f have maximal curvature corresponds to **corners** in the picture. This is useful when **tracking** or **identifying** objects.

In this picture of John Harvard, software was looking for level curves for each color and started to draw at points where the curvature of the curves is large then follow the level curve.

Homework

- 1 Find the arc length of the curve

$$\vec{r}(t) = \langle t^2, \sin(t) - t \cos(t), \cos(t) + t \sin(t) \rangle ,$$

where the time parameter satisfies $0 \leq t \leq \pi$.

- 2 Find the curvature of $\vec{r}(t) = \langle e^t \cos(t), e^t \sin(t), t \rangle$ at the point $(1, 0, 0)$.
- 3 Find the vectors $\vec{T}(t)$, $\vec{N}(t)$ and $\vec{B}(t)$ for the curve $\vec{r}(t) = \langle t^2, t^3, 0 \rangle$ for $t = 2$. Do the vectors depend continuously on t for all t ?
- 4 Let $\vec{r}(t) = \langle t, t^2 \rangle$. Find the equation for the **caustic**

$$\vec{s}(t) = \vec{r}(t) + \frac{\vec{N}(t)}{\kappa(t)}$$

which is known also as the **evolute** of the curve.

- 5 If $\vec{r}(t) = \langle -\sin(t), \cos(t) \rangle$ is the boundary of a coffee cup and light enters in the direction $\langle -1, 0 \rangle$, then light focuses inside the cup on a curve which is called the **coffee cup caustic**. The light ray travels after the reflection for length $\sin(\theta)/(2\kappa)$ until it reaches the caustic. Find a parameterization of the caustic.
